Create a frontend with provided mocks and existing code. Integrate the designs and UI as expected.

- Convert Sending email using SMTP service (using email and password)

- After sending email - in email ask user to click on link and open create password after that. Meaning example user signup and email sent > Now in email ask user to click on the link and then ask user to set password. And the password set successfully redirects users to the login page. [here also create one more field in the database of email_verified true/false and if the user set password successfully then set it to true or false. Also that link which is sent to verify in email will have validity of 1hr then it will expire. If it expires then clicking the link will ask the user to resend the link again. Handle such events and use cases accordingly]

For Register/Login transition use this reference here --- Click here
For background effects apply the background this one reference here - Click here

- After user Registration sends email to user for verification and clicking it setting password once user clicks the link which is sent in email then loads dashboard.
For sending email use SMTP service.

_____

This task includes logic improvements and to test the developer's accuracy to eye catch the details for the product. We're a very polished product based company that adores the eye of perfectionists and look forward to maintaining the best environment for developers and our customers. Task is designed to validate the developer's developing pattern and the attention to details.
